

What are Data Types

PHP (Hypertext Preprocessor) is a dynamically typed language, which means that variable data types are determined at runtime.

Variables can store data of different types, and different data types can do different things.

PHP supports the following data types:

- 1.String
- 2.Integer
- 3.Float (floating point numbers - also called double)
- 4.Boolean
- 5.Array
- 6.Object
- 7.NULL

PHP supports typecasting, allowing you to explicitly convert a variable from one type to another in certain situations. PHP also has the mixed type, which means a variable can accept multiple types.

Getting the Data Type

You can get the data type of any object by using the **var_dump()** function.
